- 13.18 Suppose you are given a bag containing n unbiased coins. You are told that n 1 of these coins are normal, with heads on one side and tails on the other, whereas one coin is a fake, with heads on both sides.
- a. Suppose you reach into the bag, pick out a coin at random, flip it, and get a head. What is the (conditional) probability that the coin you chose is the fake coin?
- b. Suppose you continue flipping the coin for a total of k times after picking it and see k heads. Now what is the conditional probability that you picked the fake coin?
- c. Suppose you wanted to decide whether the chosen coin was fake by flipping it k times. The decision procedure returns fake if all k flips come up heads; otherwise it returns normal. What is the (unconditional) probability that this procedure makes an error?
- a. Suppose you reach into the bag, pick out a coin at random, flip it, and get a head. What is the (conditional) probability that the coin you chose is the fake coin?

```
Using Bayes Rule:
```

```
P(fake \mid head) = P(head \mid fake) \times P(fake) / P(head)
P(head \mid fake) = 1
P(fake) = 1/n
```

A number of n coins presents a total of 2n faces where n+1 faces are heads and n-1 faces are tails.

$$P(head) = (n+1)/2n$$

With the previous data we can calculate P(fake | head)

$$P(fake \mid head) = 1 \times 1/n / ((n+1)/2n) = 2/(n+1)$$

b. Suppose you continue flipping the coin for a total of k times after picking it and see k heads. Now what is the conditional probability that you picked the fake coin?

Using conditional probabilities:

```
P(Fake \mid heads_k) = \delta \times P(fake \mid heads_k); P(\neg fake \mid heads_k) > \\ P(Fake \mid heads_k) = \delta \times P(heads_k \mid fake) \times P(fake); P(heads_k \mid \neg fake) \times P(\neg fake) > \\ P(Fake \mid heads_k) = \delta \times P(heads_k \mid fake) \times 1/n; P(heads_k \mid \neg fake) \times (n-1)/n > \\ P(Fake \mid heads_k) = \delta \times 1 \times 1/n; 1/2^k \times (n-1)/n > \\ P(Fake \mid heads_k) = \delta \times 1/n; (n-1)/(n \times 2^k) > \\ \delta \times (1/n + (n-1)/(n \times 2^k)) = 1 \\ \delta = (n \times 2^k) / (2^k + n - 1) \\ P(Fake \mid heads_k) = \langle (n \times 2^k) / (2^k + n - 1) \times (1/n); (n \times 2^k) / (2^k + n - 1) \times ((n-1)/(n \times 2^k)) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid heads_k) = \langle 2^k / (2^k + n - 1); (n-1) / (2^k + n - 1) > \\ P(Fake \mid hea
```

Using probability and combinatorial theories:

Number of atomic events for 1 coin: 2^k Number of atomic events for n coins: $n \times 2^k$ Number of atomic events with the fake coin: 2^k

Number of atomic events with all heads: atomic events with fake coin + atomic events with normal coins Number of atomic events with all heads: $2^k + (n-1)$

$$P(fake \mid heads_k) = atomic \ events \ with fake \ coin \mid atomic \ events \ where \ we see \ all \ heads$$

 $P(fake \mid heads_k) = 2^k \mid (2^k + n - 1)$

$$P(\neg fake \mid heads_k) = atomic \ events \ with \ normal \ coin \mid atomic \ events \ where \ we see \ all \ heads$$

 $P(\neg fake \mid heads_k) = (n-1) \mid (2^k + n - 1)$

c. Suppose you wanted to decide whether the chosen coin was fake by flipping it k times. The decision procedure returns fake if all k flips come up heads; otherwise it returns normal. What is the (unconditional) probability that this procedure makes an error?

Using the product rule:

$$P(\neg fake, heads_k) = P(heads_k | \neg fake) \times P(\neg fake)$$

 $P(\neg fake, heads_k) = 1/2^k \times (n-1)/n = (n-1)/(n \times 2^k)$

Using probabilities:

Number of atomic events where we see k heads and the coin is not fake: n-1 Sample space size: $n \times 2^k$

$$P(\neg fake, heads_k) = (n-1)/(n \times 2^k)$$
